8279, 8279-5
PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

- **MCS-85™ Compatible 8279-5**
- **Simultaneous Keyboard Display Operations**
- **Scanned Keyboard Mode**
- **Scanned Sensor Mode**
- **Strobed Input Entry Mode**
- **8 Character Keyboard FIFO**
- **2 Key Lockout or N Key Rollover with Contact Debounce**
- **Dual 8 or 16 Numerical Display**
- **Single 16 Character Display**
- **Right or Left Entry 16 Byte Display RAM**
- **Mode Programmable from CPU**
- **Programmable Scan Timing**
- **Interrupt Output on Key Entry**

The 8279 is a general purpose programmable keyboard and display I/O interface device designed for use with Intel® microprocessors. The keyboard portion can provide a scanned interface to a 64 contact key matrix which can be expanded to 128. The keyboard portion will also interface to an array of sensors or a strobed interface keyboard, such as the Hall effect and Ferrite variety. Key depressions can be 2 key lockout or N key rollover. Keyboard entries are debounced and strobed in an 8 character FIFO. If more than 8 characters are entered, over run status is set. Key entries set the interrupt output line to the CPU.

The display portion provides a scanned display interface for LED, incandescent and other popular display technologies. Both numeric and alphanumeric segment displays may be used as well as simple indicators. The 8279 has a 16 x 8 display RAM which can be organized into a dual 16 x 4. The RAM can be loaded or interrogated by the CPU. Both right entry, calculator and left entry typewriter display formats are possible. Both read and write of the display RAM can be done with auto-increment of the display RAM address.

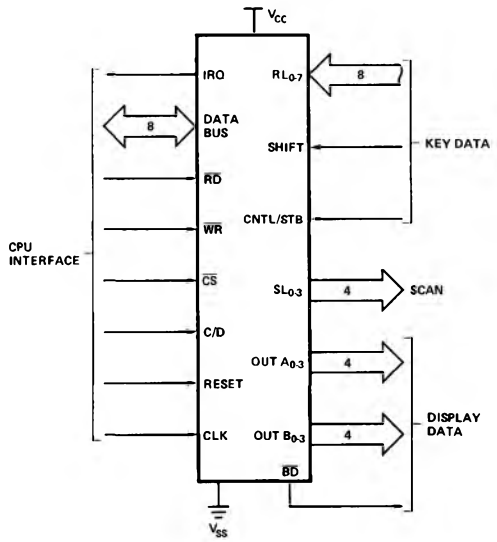

PIN CONFIGURATION

PIN NAMES

NAME	I/O	FUNCTION
DB_{0-7}	I/O	DATA BUS (BI-DIRECTIONAL)
CLK	I	CLOCK INPUT
RESET	I	RESET INPUT
$\overline{CS}$	I	CHIP SELECT
$\overline{RD}$	I	READ INPUT
$\overline{WR}$	I	WRITE INPUT
A_0	I	BUFFER ADDRESS
IRQ	O	INTERRUPT REQUEST OUTPUT
SL_{0-3}	O	SCAN LINES
RL_{0-7}	I	RETURN LINES
SHIFT	I	SHIFT INPUT
CNTL/STB	I	CONTROL/STROBE INPUT
$OUT\ A_{0-3}$	O	DISPLAY (A) OUTPUTS
$OUT\ B_{0-3}$	O	DISPLAY (B) OUTPUTS
$\overline{BD}$	O	BLANK DISPLAY OUTPUT

8279 BASIC FUNCTIONAL DESCRIPTION

Introduction

Since data input and display are an integral part of many microprocessor designs, the system designer needs an interface that can control these functions without placing a large load on the CPU. The 8279 provides this function for 8-bit microprocessors.

The 8279 has two sections: keyboard and display. The keyboard section can interface to regular typewriter style keyboards or random toggle or thumb switches. The display section drives alphanumeric displays or a bank of indicator lights. Thus the CPU is relieved from scanning the keyboard or refreshing the display.

The 8279 is designed to directly connect to the microprocessor bus. The CPU can program all operating modes for the 8279. These modes include:

Input Modes

- Scanned Keyboard — with encoded (8 x 8 x 4 key keyboard) or decoded (4 x 8 x 4 key keyboard) scan lines. A key depression generates a 6-bit encoding of key position. Position and shift and control status are stored in the FIFO. Keys are automatically debounced with 2-key lockout or N-key rollover.
- Scanned Sensor Matrix — with encoded (8 x 8 matrix switches) or decoded (4 x 8 matrix switches) scan lines. Key status (open or closed) stored in RAM addressable by CPU.
- Strobed Input — Data on return lines during control line strobe is transferred to FIFO.

Output Modes

- 8 or 16 character multiplexed displays that can be organized as dual 4-bit or single 8-bit.
- Right entry or left entry display formats.

Other features of the 8279 include:

- Mode programming from the CPU.
- Programmable clock to match the 8279 scan times to the CPU cycle time.
- Interrupt output to signal CPU when there is keyboard or sensor data available.
- An 8 byte FIFO to store keyboard information.
- 16 byte internal Display RAM for display refresh. This RAM can also be read by the CPU.

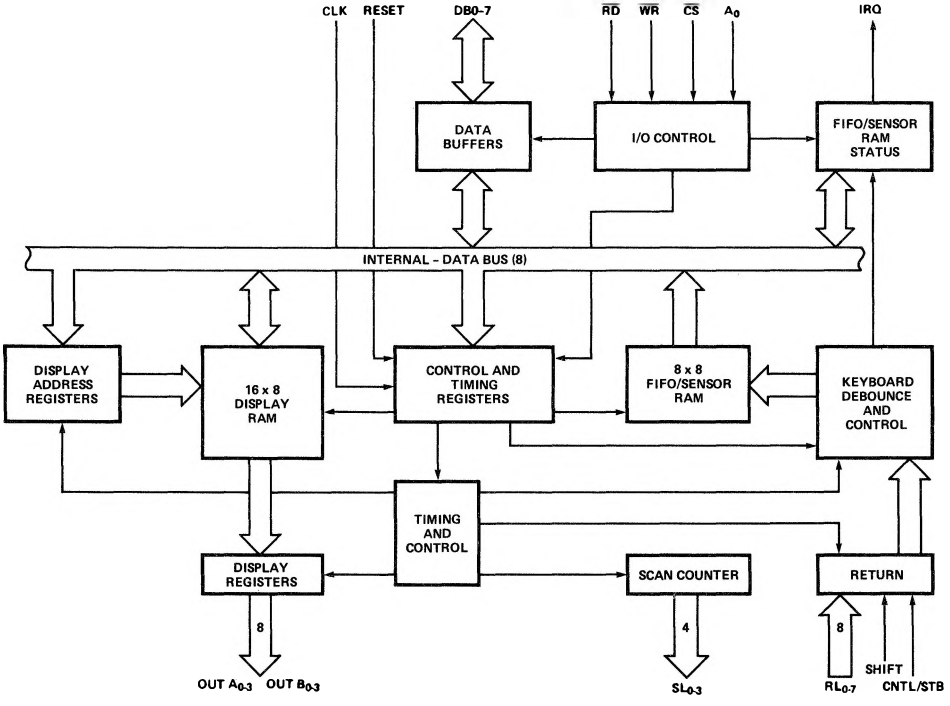

FIGURE 1. 8279 BLOCK DIAGRAM

PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

Hardware Description

The 8279 is packaged in a 40 pin DIP. The following is a functional description of each pin.

No. Of Pins	Designation	Function
8	DB_0-DB_7	Bi-directional data bus. All data and commands between the CPU and the 8279 are transmitted on these lines.
1	CLK	Clock from system used to generate internal timing.
1	RESET	A high signal on this pin resets the 8279.
1	$\overline{CS}$	Chip Select. A low on this pin enables the interface functions to receive or transmit.
1	A_0	Buffer Address. A high on this line indicates the signals in or out are interpreted as a command or status. A low indicates that they are data.
2	$\overline{RD}$, $\overline{WR}$	Input/Output read and write. These signals enable the data buffers to either send data to the external bus or receive it from the external bus.
1	IRQ	Interrupt Request. In a keyboard mode, the interrupt line is high when there is data in the FIFO/Sensor RAM. The interrupt line goes low with each FIFO/Sensor RAM read and returns high if there is still information in the RAM. In a sensor mode, the interrupt line goes high whenever a change in a sensor is detected.
2	V_{SS}, V_{CC}	Ground and power supply pins.
4	SL_0-SL_3	Scan Lines which are used to scan the key switch or sensor matrix and the display digits. These lines can be either encoded (1 of 16) or decoded (1 of 4).
8	RL_0-RL_7	Return line inputs which are connected to the scan lines through the keys or sensor switches. They have active internal pullups to keep them high until a switch closure pulls one low. They also serve as an 8-bit input in the Strobed Input mode.
1	SHIFT	The shift input status is stored along with the key position on key closure in the Scanned Keyboard modes. It has an active internal pullup to keep it high until a switch closure pulls it low.
1	CNTL/STB	For keyboard modes this line is used as a control input and stored like status on a key closure. The line is also the strobe line that enters the data into the FIFO in the Strobed Input mode. (Rising Edge). It has an active internal pullup to keep it high until a switch closure pulls it low.
4 4	OUT A_0-OUT A_3 OUT B_0-OUT B_3	These two ports are the outputs for the 16 x 4 display refresh registers. The data from these outputs is synchronized to the scan lines (SL_0-SL_3) for multiplexed digit displays. The two 4 bit ports may be blanked independently. These two ports may also be considered as one 8 bit port.
1	$\overline{BD}$	Blank Display. This output is used to blank the display during digit switching or by a display blanking command.

Principles of Operation

The following is a description of the major elements of the 8279 Programmable Keyboard/Display interface device. Refer to the block diagram in Figure 1.

I/O Control and Data Buffers

The I/O control section uses the $\overline{CS}$, A_0, $\overline{RD}$ and $\overline{WR}$ lines to control data flow to and from the various internal registers and buffers. All data flow to and from the 8279 is enabled by $\overline{CS}$. The character of the information, given or desired by the CPU, is identified by A_0. A logic one means the information is a command or status. A logic zero means the information is data. $\overline{RD}$ and $\overline{WR}$ determine the direction of data flow through the Data Buffers. The Data Buffers are bi-directional buffers that connect the internal bus to the external bus. When the chip is not selected ($\overline{CS}$ = 1), the devices are in a high impedance state. The drivers input during $WR \bullet \overline{CS}$ and output during $RD \bullet \overline{CS}$.

Control and Timing Registers and Timing Control

These registers store the keyboard and display modes and other operating conditions programmed by the CPU. The modes are programmed by presenting the proper command on the data lines with $A_0 = 1$ and then sending a $\overline{WR}$. The command is latched on the rising edge of $\overline{WR}$.

PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

The command is then decoded and the appropriate function is set. The timing control contains the basic timing counter chain. The first counter is a ÷ N prescaler that can be programmed to match the CPU cycle time to the internal timing. The prescaler is software programmed to a value between 2 and 31. A value which yields an internal frequency of 100 kHz gives a 5.1 ms keyboard scan time and a 10.3 ms debounce time. The other counters divide down the basic internal frequency to provide the proper key scan, row scan, keyboard matrix scan, and display scan times.

Scan Counter

The scan counter has two modes. In the encoded mode, the counter provides a binary count that must be externally decoded to provide the scan lines for the keyboard and display. In the decoded mode, the scan counter decodes the least significant 2 bits and provides a decoded 1 of 4 scan. Note than when the keyboard is in decoded scan, so is the display. This means that only the first 4 characters in the Display RAM are displayed.

In the encoded mode, the scan lines are active high outputs. In the decoded mode, the scan lines are active low outputs.

Return Buffers and Keyboard Debounce and Control

The 8 return lines are buffered and latched by the Return Buffers. In the keyboard mode, these lines are scanned, looking for key closures in that row. If the debounce circuit detects a closed switch, it waits about 10 msec to check if the switch remains closed. If it does, the address of the switch in the matrix plus the status of SHIFT and CONTROL are transferred to the FIFO. In the scanned Sensor Matrix modes, the contents of the return lines is directly transferred to the corresponding row of the Sensor RAM (FIFO) each key scan time. In Strobed Input mode, the contents of the return lines are transferred to the FIFO on the rising edge of the CNTL/STB line pulse.

FIFO/Sensor RAM and Status

This block is a dual function 8 x 8 RAM. In Keyboard or Strobed Input modes, it is a FIFO. Each new entry is written into successive RAM positions and each is then read in order of entry. FIFO status keeps track of the number of characters in the FIFO and whether it is full or empty. Too many reads or writes will be recognized as an error. The status can be read by an $\overline{RD}$ with $\overline{CS}$ low and A_0 high. The status logic also provides an IRQ signal when the FIFO is not empty. In Scanned Sensor Matrix mode, the memory is a Sensor RAM. Each row of the Sensor RAM is loaded with the status of the corresponding row of sensor in the sensor matrix. In this mode, IRQ is high if a change in a sensor is detected.

Display Address Registers and Display RAM

The Display Address Registers hold the address of the word currently being written or read by the CPU and the two 4-bit nibbles being displayed. The read/write addresses are programmed by CPU command. They also can be set to auto increment after each read or write. The Display RAM can be directly read by the CPU after the correct mode and address is set. The addresses for the A and B nibbles are automatically updated by the 8279 to match data entry by the CPU. The A and B nibbles can be entered independently or as one word, according to the mode that is set by the CPU. Data entry to the display can be set to either left or right entry. See Interface Considerations for details.

Software Operation

8279 Commands

The following commands program the 8279 operating modes. The commands are sent on the Data Bus with $\overline{CS}$ low and A_0 high and are loaded to the 8279 on the rising edge of $\overline{WR}$.

Keyboard/Display Mode Set

	MSB							LSB
Code:	0	0	0	D	D	K	K	K

Where DD is the Display Mode and KKK is the Keyboard Mode.

DD

0	0	8 8-bit character display — Left entry
0	1	16 8-bit character display — Left entry*
1	0	8 8-bit character display — Right entry
1	1	16 8-bit character display — Right entry

For description of right and left entry, see Interface Considerations. Note that when decoded scan is set in keyboard mode, the display is reduced to 4 characters independent of display mode set.

KKK

0	0	0	Encoded Scan Keyboard — 2 Key Lockout
0	0	1	Decoded Scan Keyboard — 2-Key Lockout
0	1	0	Encoded Scan Keyboard — N-Key Rollover
0	1	1	Decoded Scan Keyboard — N-Key Rollover
1	0	0	Encoded Scan Sensor Matrix
1	0	1	Decoded Scan Sensor Matrix
1	1	0	Strobed Input, Encoded Display Scan
1	1	1	Strobed Input, Decoded Display Scan

Program Clock

Code:	0	0	1	P	P	P	P	P

Where PPPPP is the prescaler value 2 to 31. The programmable prescaler divides the external clock by PPPPP to get the basic internal frequency. Choosing a divisor that yields 100 KHz will give the specified scan and debounce times. Default after a reset pulse (but not a program clear) is 31.

Read FIFO/Sensor RAM

Code:	0	1	0	AI	X	A	A	A	X = Don't Care

Where AI is the Auto-Increment flag for the Sensor RAM and AAA is the row that is going to be read by the CPU. AI and AAA are used only if the mode is set to Sensor Matrix. This command is used to specify that the source of data reads ($\overline{CS} \bullet RD \bullet \overline{A_0}$) by the CPU is the FIFO/Sensor RAM. No additional commands are necessary as long as

*Default after reset.

PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

data is desired from the FIFO/Sensor RAM. Another command is necessary if reading is desired from a different row than has been selected. If AI is a one, the row select counter will be incremented after each read so the next read will be from the next Sensor RAM row.

In the Auto Increment mode for reading data from the FIFO/Sensor RAM, each read advances the address by one so that the next read is from the next character. This Auto Incrementing has no effect on the display.

Read Display RAM

Code:

0	1	1	AI	A	A	A	A

Where AI is the Auto-Increment flag for the Display RAM and AAAA is the character that the CPU is going to read next. Since the CPU uses the same counter for reading and writing, this command also sets the next write location and Auto-Increment mode. This command is used to specify the display RAM as the data source for CPU data reads. If AI is set, the character address will be incremented after each read (or write) so that the next read (or write) will be from (to) the next character.

Write Display RAM

Code:

1	0	0	AI	A	A	A	A

Where AI is the Auto-Increment flag for the Display RAM and AAAA is the character that the CPU is going to write next. The addressing and Auto-Increment are identical to Read Display RAM. The difference is that Write Display RAM does not affect the source of CPU reads. The CPU will read from whichever RAM (Display or FIFO/Sensor) was last specified. This command will, however, change the location the next Display RAM read will be from if that source was specified.

Display Write Inhibit/Blanking

Code:

1	0	1	X	IW	IW	BL	BL
				A	B	A	B

Where IW is Inhibit Writing (nibble A or B) and BL is Blanking (nibble A or B). If the display is being used as a dual 4-bit display, then it is necessary to mask one of the 4-bit halves so that entries to the Display from the CPU do not affect the other half. The IW flags allow the programmer to do this. It is also useful to be able to blank either half when that half is not to be displayed. The BL flags blank the display. The next command sets the output code to be used as a "blank". Default after reset is all zeros. Note that to blank a display formatted as a single 8-bit output, it is necessary to set both BL flags to entirely blank the display. A "1" sets the flag. Reissuing the command with a "0" resets the flag.

Clear

Code:

1	1	0	C_D	C_D	C_D	C_F	C_A

Where C_D is Clear Display, C_F is Clear FIFO Status (including interrupt), and C_A is Clear All. C_D is used to clear all positions of the Display RAM to a programmable code. All ones, all zeros and hexadecimal 20 are possible. The 2 least significant bits of C_D are also used to specify the blanking code (see below).

C_D C_D	
0 X	All Zeros (X = Don't Care)
1 0	AB = Hex 20 (0010 0000)
1 1	All Ones

Enable clear display when = 1 (or by C_A = 1)

Clearing the display takes one display scan. During this time the CPU cannot write to the Display RAM. The MSB of the FIFO status word will be set during this time.

C_F set the FIFO status to empty and resets the interrupt output line. After execution of a clear command with C_F set, the Sensor Matrix mode RAM pointer will be set to row 0.

C_A has the combined effect of C_D and C_F. C_A uses the C_D clearing code to determine how to clear the Display RAM. C_A also resets the internal timing chain to resynchronize it.

End Interrupt/Error Mode Set

Code:

1	1	1	E	X	X	X	X

X = Don't care.

For the sensor matrix modes this command lowers the IRQ line and enables further writing into RAM. (The IRQ line would have been raised upon the detection of a change in a sensor value. This would have also inhibited further writing into the RAM until reset).

For the N-key rollover mode — if the E bit is programmed to "1" the chip will operate in the special Error mode. (For further details, see Interface Considerations Section.)

Status Word

The status word contains the FIFO status, error, and display unavailable signals. This word is read by the CPU when A_0 is high and $\overline{CS}$ and $\overline{RD}$ are low. See Interface Considerations for more detail on status word.

Data Read

Data is read when A_0, $\overline{CS}$ and $\overline{RD}$ are all low. The source of the data is specified by the Read FIFO or Read Display commands. The trailing edge of $\overline{RD}$ will cause the address of the RAM being read to be incremented if the Auto-Increment flag is set. FIFO reads always increment (if no error occurs) independent of AI.

Data Write

Data that is written with A_0, $\overline{CS}$ and $\overline{WR}$ low is always written to the Display RAM. The address is specified by the latest Read Display or Write Display command. Auto-Incrementing on the rising edge of $\overline{WR}$ occurs if AI set by the latest display command.

PRELIMINAR
Notice: This is not a final specification. Some parametric limits are subject to change.

INTERFACE CONSIDERATIONS

A. Scanned Keyboard Mode, 2-Key Lockout

There are three possible combinations of conditions that can occur during debounce scanning. When a key is depressed, the debounce logic is set. A full scan of the keyboard is ignored, then other depressed keys are looked for. If none are encountered, it is a single key depression and the key position is entered into the FIFO along with the status of CNTL and SHIFT lines. If the FIFO was empty, IRQ will be set to signal the CPU that there is an entry in the FIFO. If the FIFO was full, the key will not be entered and the error flag will be set. If another closed switch is encountered, no entry to the FIFO can occur. If all other keys are released before this one, then it will be entered to the FIFO. If this key is released before any other, it will be entirely ignored. A key is entered to the FIFO only once per depression, no matter how many keys were pressed along with it or in what order they were released. If two keys are depressed within the debounce cycle, it is a simultaneous depression. Neither key will be recognized until one key remains depressed alone. The last key will be treated as a single key depression.

B. Scanned Keyboard Mode, N-Key Rollover

With N-key Rollover each key depression is treated independently from all others. When a key is depressed, the debounce circuit waits 2 keyboard scans and then checks to see if the key is still down. If it is, the key is entered into the FIFO. Any number of keys can be depressed and another can be recognized and entered into the FIFO. If a simultaneous depression occurs, the keys are recognized and entered according to the order the keyboard scan found them.

C. Scanned Keyboard — Special Error Modes

For N-key rollover mode the user can program a special error mode. This is done by the "End Interrupt/Error Mode Set" command. The debounce cycle and key-validity check are as in normal N-key mode. If during a single debounce cycle, two keys are found depressed, this is considered a simultaneous multiple depression, and sets an error flag. This flag will prevent any further writing into the FIFO and will set interrupt (if not yet set). The error flag could be read in this mode by reading the FIFO STATUS word. (See "FIFO STATUS" for further details.) The error flag is reset by sending the normal CLEAR command with $C_F = 1$.

D. Sensor Matrix Mode

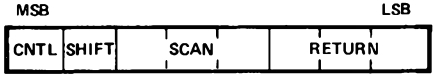

In Sensor Matrix mode, the debounce logic is inhibited. The status of the sensor switch is inputted directly to the Sensor RAM. In this way the Sensor RAM keeps an image of the state of the switches in the sensor matrix. Although debouncing is not provided, this mode has the advantage that the CPU knows how long the sensor was closed and when it was released. A keyboard mode can only indicate a validated closure. To make the software easier, the designer should functionally group the sensors by row since this is the format in which the CPU will read them.

The IRQ line goes high if any sensor value change is detected at the end of a sensor matrix scan. The IRQ line is cleared by the first data read operation if the Auto-Increment flag is set to zero, or by the End Interrupt command if the Auto-Increment flag is set to one.

Note: Multiple changes in the matrix Addressed by ($SL_{0-3} = 0$) may cause multiple interrupts. ($SL_0 = 0$ in the Decoded Mode). Reset may cause the 8279 to see multiple changes.

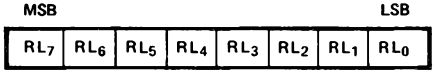

E. Data Format

In the Scanned Keyboard mode, the character entered into the FIFO corresponds to the position of the switch in the keyboard plus the status of the CNTL and SHIFT lines. CNTL is the MSB of the character and SHIFT is the next most significant bit. The next three bits are from the scan counter and indicate the row the key was found in. The last three bits are from the column counter and indicate to which return line the key was connected.

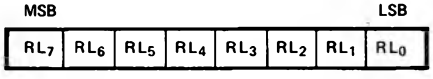

SCANNED KEYBOARD DATA FORMAT

In Sensor Matrix mode, the data on the return lines is entered directly in the row of the Sensor RAM that corresponds to the row in the matrix being scanned. Therefore, each switch postion maps directly to a Sensor RAM position. The SHIFT and CNTL inputs are ignored in this mode. Note that switches are not necessarily the only thing that can be connected to the return lines in this mode. Any logic that can be triggered by the scan lines can enter data to the return line inputs. Eight multiplexed input ports could be tied to the return lines and scanned by the 8279.

In Strobed Input mode, the data is also entered to the FIFO from the return lines. The data is entered by the rising edge of a CNTL/STB line pulse. Data can come from another encoded keyboard or simple switch matrix. The return lines can also be used as a general purpose strobed input.

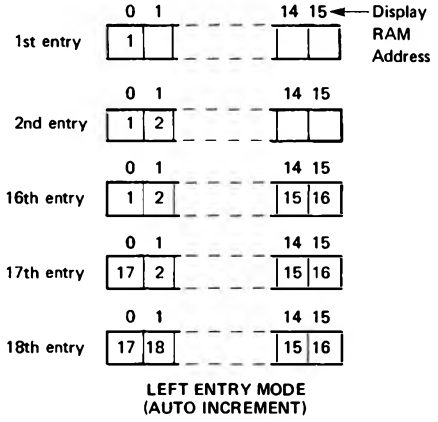

F. Display

Left Entry

Left Entry mode is the simplest display format in that each display position directly corresponds to a byte (or nibble) in the Display RAM. Address 0 in the RAM is the left-most display character and address 15 (or address 7 in 8 character display) is the right most display character. Entering characters from position zero causes the display to fill from the left. The 17th (9th) character is entered back in the left most position and filling again proceeds from there.

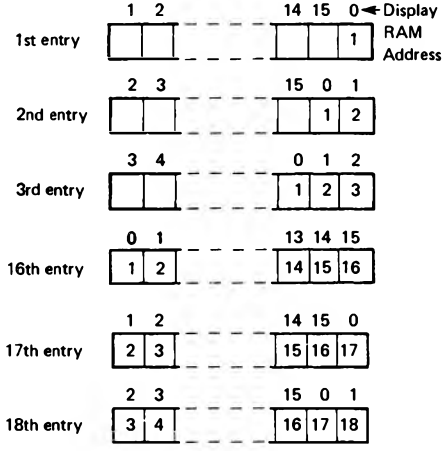

PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

LEFT ENTRY MODE
(AUTO INCREMENT)

Right Entry

Right entry is the method used by most electronic calculators. The first entry is placed in the right most display character. The next entry is also placed in the right most character after the display is shifted left one character. The left most character is shifted off the end and is lost.

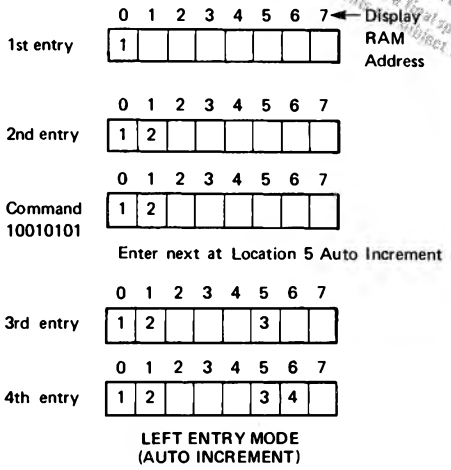

RIGHT ENTRY MODE
(AUTO INCREMENT)

Note that now the display position and register address do not correspond. Consequently, entering a character to an arbitrary position in the Auto Increment mode may have unexpected results. Entry starting at Display RAM address 0 with sequential entry is recommended.

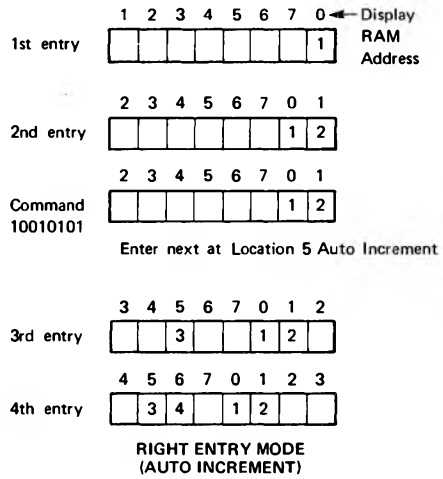

Auto Increment

In the Left Entry mode, Auto Incrementing causes the address where the CPU will next write to be incremented by one and the character appears in the next location. With non-Auto Incrementing the entry is both to the same RAM address and display position. Entry to an arbitrary address in the Auto Increment mode has no undesirable side effects and the result is predictable:

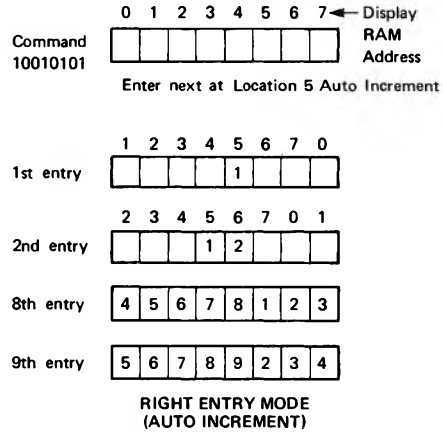

LEFT ENTRY MODE
(AUTO INCREMENT)

In the Right Entry mode, Auto Incrementing and non Incrementing have the same effect as in the Left Entry except if the address sequence is interrupted:

RIGHT ENTRY MODE
(AUTO INCREMENT)

Starting at an arbitrary location operates as shown below:

RIGHT ENTRY MODE
(AUTO INCREMENT)

PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

Entry appears to be from the initial entry point.

8/16 Character Display Formats

If the display mode is set to an 8 character display, the on duty-cycle is double what it would be for a 16 character display (e.g., 5.1 ms scan time for 8 characters vs. 10.3 ms for 16 characters with 100 kHz internal frequency).

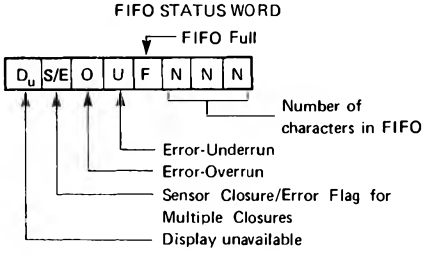

G. FIFO Status

FIFO status is used in the Keyboard and Strobed Input modes to indicate the number of characters in the FIFO and to indicate whether an error has occurred. There are two types of errors possible: overrun and underrun. Overrun occurs when the entry of another character into a full FIFO is attempted. Underrun occurs when the CPU tries to read an empty FIFO.

The FIFO status word also has a bit to indicate that the Display RAM was unavailable because a Clear Display or Clear All command had not completed its clearing operation.

In a Sensor Matrix mode, a bit is set in the FIFO status word to indicate that at least one sensor closure indication is contained in the Sensor RAM.

In Special Error Mode the S/E bit is showing the error flag and serves as an indication to whether a simultaneous multiple closure error has occurred.
